Important concepts, symbols, and equations

Robot statics: $\tau = J_*^T(\theta) \mathcal{F}_*$, where $*$ = s or b .

Proper interpretation: if a wrench $-\mathcal{F}$ is applied to the last link, then $\tau = J^T(\theta) \mathcal{F}$ is required to resist it.

If $J(\theta)$ has rank 6, then the robot can *actively* generate an end-effector wrench in any direction. The static equation is useful for force control.

If $J(\theta)$ has rank $k < 6$, then any applied wrench can be decomposed into the sum of components in k directions requiring motors to resist and components in $6 - k$ directions that are resisted by the bearings.

What is the 6×3 Jacobian J_b ? What is its rank?
 What wrenches can be resisted without using the motors?

A linear force f to the right is applied to link 3 at the point shown. What is the corresponding wrench $-\mathcal{F}_b$? τ needed to resist it?
